LESSON ASSIGNMENT

LESSON 11
The Human Nervous System.

TEXT ASSIGNMENT
Paragraphs 11-1 through 11-39.

LESSON OBJECTIVES
After completing this lesson, you should be able to:

11-1. Name and identify two types of nervous tissues.

11-2. Name three functions for which nervous tissues are specialized.

11-3. Define neuron, dendrite, and axon.

11-4. When given the shape, diameter, or function, name the corresponding type of neuron.

11-5. Describe neuron "connections," including the synapse and the neuromuscular junction.

11-6. Name and identify the three major divisions of the human nervous system; name the two major subdivisions of the CNS.

11-7. Name and briefly describe the three major subdivisions of the human brain; name and locate the four ventricles and their connecting channels.

11-8. Describe the spinal cord, including the two enlargements, elements of its cross section, and the surrounding vertebral canal.

11-9. Describe the meninges and the skeletal coverings of the CNS.

11-10. Name and identify the main arteries and veins of the brain and briefly describe the blood supply of the spinal cord.

11-11. Describe the formation of cerebrospinal fluid (CSF) and the path of CSF flow.
11-12. Define **peripheral nervous system** (PNS) and nerve; name and briefly describe two categories of PNS nerves; describe the anatomy of a "typical" spinal nerve; define reflex and reflex arc; briefly describe the components of the general reflex arc.

11-13. Define **autonomic nervous system** (ANS) and visceral organs; briefly describe efferent pathways of the ANS; name the major divisions of the human ANS; briefly describe the major activities of the human ANS for the thoraco-lumbar and cranio-sacral outflows; briefly describe the first and second neurons, innervations, and effects in each case.

11-14. Define **pathway**, **neuraxis**, **sensor pathway**, and **motor pathway**; briefly describe levels of control, pyramidal and extra-pyramidal motor pathways, and sensory pathways; and give examples of **general senses** and **special senses**.

11-15. Briefly describe the sensory receptors and sensory pathways for the special senses of smell and taste.

11-16. Describe the structures of the bulbus oculi, the orbit, and the adnexa.

11-17. Describe the structures of the external ear, the middle ear, and the internal ear.

11-18. Describe the structures of the sacculus, utriculus, semicircular ducts, and the vestibular nerve.

11-19. Describe controls in the human nervous system.

**SUGGESTION**

After completing the assignment, complete the exercises at the end of this lesson. These exercises will help you to achieve the lesson objectives.
LESSON 11
THE HUMAN NERVOUS SYSTEM

Section I. INTRODUCTION

11-1. NERVOUS TISSUES

There are two types of nervous tissues--the neurons (nerve cells) and glia (neuroglia). See paragraph 2-17. The neuron is the basic structural unit of the nervous system. The glia are cells of supporting tissue for the nervous system. There are several different types of glia, but their general function is support (physical, nutritive, etc.).

11-2. SPECIALIZATION

Nervous tissues are specialized to:

a. Receive Stimuli. Cells receiving stimuli are said to be "irritable" (as are all living cells to a degree).

b. Transmit Information.

c. "Store" Information. The storing of information is called memory.

Section II. THE NEURON AND ITS "CONNECTIONS"

11-3. DEFINITION

A neuron (figure 11-1) is a nerve cell body and all of its processes (branches).

11-4. NEURON CELL BODY

The neuron cell body is similar to that of the "typical" animal cell described in lesson 1.
11-5. **NEURON PROCESSES**

There are two types of neuron processes--dendrites and axons.

a. **Dendrite.** A dendrite is a neuron process which carries impulses **toward** the cell body. Each neuron may have one or more dendrites. Dendrites receive information and transmit (carry) it to the cell body.

b. **Axon.** An axon is a neuron process which transmits information **from** the cell body to the next unit. Each neuron has only one axon.

c. **Information Transmission.** Information is carried as electrical impulses along the length of the neuron.

d. **Coverings.** Some neuron processes have a covering which is a series of Schwann cells, interrupted by nodes (thin spots). This gives the neuron process the appearance of links of sausage. The Schwann cells produce a lipid (fatty) material called **myelin.** This myelin acts as an electrical insulator during the transmission of impulses.
11-6. TYPES OF NEURONS

Neurons may be identified according to shape, diameter of their processes, or function.

a. According to Shape. A pole is the point where a neuron process meets the cell body. To determine the type according to shape, count the number of poles.

(1) Multipolar neurons. Multipolar neurons have more than two poles (one axon and two or more dendrites).

(2) Bipolar neurons. Bipolar neurons have two poles (one axon and one dendrite).

(3) Unipolar neurons. Unipolar neurons have a single process which branches into a T-shape. One arm is an axon; the other is a dendrite.

b. According to Diameter (Thickness) of Processes. Neurons may be rated according to the thickness of myelin surrounding the axon. In order of decreasing thickness, they are rated A (thickest), B, and C (thinnest). The thickness affects the rate at which impulses are transmitted. The thickest are fastest. The thinnest are slowest.

c. According to Function.

(1) Sensory neurons. In sensory neurons, impulses are transmitted from receptor organs (for pain, vision, hearing, etc.) to the central nervous system (CNS).

(2) Motor neurons. In motor neurons, impulses are transmitted from the CNS to muscles and glands (effector organs).

(3) Interneurons. Interneurons transmit information from one neuron to another. An interneuron "connects" two other neurons.

(4) Others. There are other, more specialized types, for example, in the CNS.

11-7. NEURON "CONNECTIONS"

A neuron may "connect" either with another neuron or with a muscle fiber. A phrase used to describe such "connections" is "continuity without contact." Neurons do not actually touch. There is just enough space to prevent the electrical transmission from crossing from the first neuron to the next. This space is called the synaptic cleft. Information is transferred across the synaptic cleft by chemicals called neurotransmitters. Neurotransmitters are manufactured and stored on only one side of the cleft. Because of this, information flows in only one direction across the cleft.
a. **The Synapse.** A synapse (figure 11-2) is a "connection" between two neurons.

![Figure 11-2. A synapse.](image)

(1) **First neuron.** An axon terminates in tiny branches. At the end of each branch is found a terminal bulb. Synaptic vesicles (bundles of neurotransmitter) are located within each terminal bulb. That portion of the terminal bulb which faces the synaptic cleft is thickened and is called the presynaptic membrane. This is the membrane through which neurotransmitters pass to enter the synaptic cleft.

(2) **Synaptic cleft.** The synaptic cleft is the space between the terminal bulb of the first neuron and the dendrite or cell body of the second neuron.

(3) **Second neuron.** The terminal bulb of the first neuron lies near a site on a dendrite or the cell body of the second neuron. The membrane at this site on the second neuron is known as the postsynaptic membrane. Within the second neuron is a chemical that inactivates the used neurotransmitter.

b. **The Neuromuscular Junction.** A neuromuscular junction (figure 11-3) is a "connection" between the terminal of a motor neuron and a muscle fiber. The neuromuscular junction has an organization identical to a synapse. However, the bulb is larger. The postsynaptic membrane is also larger and has foldings to increase its surface area.
Figure 11-3. A neuromuscular junction.

1. **Motor neuron.** The axon of a motor neuron ends as it reaches a striated muscle fiber (of a skeletal muscle). At this point, it has a terminal bulb. Within this bulb are synaptic vesicles (bundles of neurotransmitter). The presynaptic membrane lines the surface of the terminal bulb and lies close to the muscle fiber.

2. **Synaptic cleft.** The synaptic cleft is a space between the terminal bulb of the motor neuron and the membrane of the muscle fiber.

3. **Muscle fiber.** The terminal bulb of the motor neuron protrudes into the surface of the muscle fiber. The membrane lining the synaptic space has foldings and is called the postsynaptic membrane. Beneath the postsynaptic membrane is a chemical which inactivates the used neurotransmitter.

Section III. THE HUMAN CENTRAL NERVOUS SYSTEM

11-8. **GENERAL**

The major divisions of the human nervous system are the central nervous system (CNS), the peripheral nervous system (PNS), and the autonomic nervous system.
system (ANS). The CNS is made up of the brain and spinal cord. Both the PNS and the ANS carry information to and from the central nervous system. The PNS is generally concerned with the innervation of skeletal muscles and other muscles made up of striated muscle tissue, as well as sensory information from the periphery of the body. The ANS is that portion of the nervous system concerned with control of smooth muscle, cardiac muscle, and glands. The CNS (figure 11-4) is known as central because its anatomical location is along the central axis of the body and because the CNS is central in function. If we use a computer analogy to understand that it is central in function, the CNS would be the central processing unit and other parts of the nervous system would supply inputs and transmit outputs.

Figure 11-4. The human central nervous system.
a. **Major Subdivisions of the CNS.** The major subdivisions of the CNS are the brain and the spinal cord.

b. **Coverings of the CNS.** The coverings of the CNS are skeletal and fibrous.

c. **Cerebrospinal Fluid (CSF).** The CSF is a liquid thought to serve as a cushion and circulatory vehicle within the CNS.

**11-9. THE HUMAN BRAIN**

The human brain has three major subdivisions: brainstem, cerebellum, and cerebrum. The CNS is first formed as a simple tubelike structure in the embryo. The concentration of nervous tissues at one end of the human embryo to produce the brain and head is referred to as cephalization. When the embryo is about four weeks old, it is possible to identify the early forms of the brainstem, cerebellum, and cerebrum, as well as the spinal cord. As development continues, the brain is located within the cranium (para 4-13c(1)) in the cranial cavity. See figures 11-5A and 11-5B for illustrations of the adult brain.

![Human Brain Diagram](image_url)

Figure 11-5A. Human brain (side view).
a. **The Brainstem.** The term brainstem refers to that part of the brain that would remain after removal of the cerebrum and cerebellum. The brainstem is the basal portion (portion of the base) of the brain. The brainstem can be divided as follows:

- **FOREBRAINSTEM:** thalamus
  hypothalamus

- **MIDBRAINSTEM:** corpora quadrigemina
  cerebral peduncles

- **HINDBRAINSTEM:** pons
  medulla

  (1) The brainstem is continuous with the spinal cord. Together, the brainstem and the spinal cord are sometimes known as the *neuraxis*.

  (2) The brainstem provides major relays and controls for information passing up or down the neuraxis.
(3) The 12 pairs of cranial nerves connect at the sides of the brainstem.

b. Cerebellum. The cerebellum is a spherical mass of nervous tissue attached to and covering the hindbrainstem. It has a narrow central part called the vermis and right and left cerebellar hemispheres.

(1) Peduncles. A peduncle is a stem-like connecting part. The cerebellum is connected to the brainstem with three pairs of peduncles.

(2) General shape and construction. A cross section of the cerebellum reveals that the outer cortex is composed of gray matter (cell bodies of neurons) with many folds and sulci (shallow grooves). More centrally located is the white matter (myelinated processes of neurons).

(3) Function. The cerebellum is the primary coordinator/integrator of motor actions of the body.

c. Cerebrum. The cerebrum consists of two very much enlarged hemispheres connected to each other by a special structure called the corpus callosum. Each cerebral hemisphere is connected to the brainstem by a cerebral peduncle. The surface of each cerebral hemisphere is subdivided into areas known as lobes. Each lobe is named according to the cranial bone under which it lies: frontal, parietal, occipital, and temporal.

(1) The space separating the two cerebral hemispheres is called the longitudinal fissure. The shallow grooves in the surface of the cerebrum are called sulci (sulcus, singular). The ridges outlined by the sulci are known as gyri ( gyrus, singular).

(2) The cerebral cortex is the gray outer layer of each hemisphere. The occurrence of sulci and gyri helps to increase the amount of this layer. Deeper within the cerebral hemispheres, the tissue is white. The "gray matter" represents cell bodies of the neurons. The "white matter" represents the axons.

(3) The areas of the cortex are associated with groups of related functions.

(a) For example, centers of speech and hearing are located along the lateral sulcus, at the side of each hemisphere.

(b) Vision is centered at the rear in the area known as the occipital lobe.

(c) Sensory and motor functions are located along the central sulcus, which separates the frontal and parietal lobes of each hemisphere. The motor areas are located along the front side of the central sulcus, in the frontal lobe. The sensory areas are located along the rear side of the central sulcus, in the parietal lobe.
d. **Ventricles.** Within the brain, there are interconnected hollow spaces filled with cerebrospinal fluid (CSF). These hollow spaces are known as ventricles. The right and left lateral ventricles are found in the cerebral hemispheres. The lateral ventricles are connected to the third ventricle via the interventricular foramen (of Monroe). The third ventricle is located in the forebrainstem. The fourth ventricle is in the hindbrainstem. The cerebral aqueduct (of Sylvius) is a short tube through the midbrainstem which connects the third and fourth ventricles. The fourth ventricle is continuous with the narrow central canal of the spinal cord.

11-10. **THE HUMAN SPINAL CORD**

a. **Location and Extent.** Referring to figure 4-4, you can see that the typical vertebra has a large opening called the vertebral (or spinal) foramen. Together, these foramina form the vertebral (spinal) canal for the entire vertebral column. The spinal cord, located within the spinal canal, is continuous with the brainstem. The spinal cord travels the length from the foramen magnum at the base of the skull to the junction of the first and second lumbar vertebrae.

   (1) **Enlargements.** The spinal cord has two enlargements. One is the cervical enlargement, associated with nerves for the upper members. The other is the lumbosacral enlargement, associated with nerves for the lower members.

   (2) **Spinal nerves.** A nerve is a bundle of neuron processes which carry impulses to and from the CNS. Those nerves arising from the spinal cord are spinal nerves. There are 31 pairs of spinal nerves.

b. **A Cross Section of the Spinal Cord (figure 11-6).** The spinal cord is a continuous structure which runs through the vertebral canal down to the lumbar region of the column. It is composed of a mass of central gray matter (cell bodies of neurons) surrounded by peripheral white matter (myelinated processes of neurons). The gray and white matter are thus considered columns of material. However, in a cross section, this effect of columns is lost.

   (1) **Central canal.** A very narrow canal, called the central canal, is located in the center of the spinal cord. The central canal is continuous with the fourth ventricle of the brain.

   (2) **The gray matter.** In the cross section of the spinal cord, one can see a central H-shaped region of gray matter. Each arm of the H is called a horn, resulting in two posterior horns and two anterior horns. The connecting link is called the gray commissure. Since the gray matter extends the full length of the spinal cord, these horns are actually sections of the gray columns.

   (3) **The white matter.** The peripheral portion of the spinal cord cross section consists of white matter. Since a column of white matter is a large bundle of processes, it is called a funiculus. In figure 11-6, note the anterior, lateral, and posterior funiculi.
11-11. COVERINGS OF THE CNS

The coverings of the CNS are skeletal and fibrous.

a. **Skeletal Coverings.**

(1) **Brain.** The bones of the cranium form a spherical case around the brain. The cranial cavity is the space inclosed by the bones of the cranium.

(2) **Spinal cord.** The vertebrae, with the vertebral foramina, form a cylindrical case around the spinal cord. The overall skeletal structure is the vertebral column (spine). The vertebral (spinal) canal is the space inclosed by the foramina of the vertebrae.

b. **Meninges (Fibrous Membranes).** The brain and spinal cord have three different membranes surrounding them called meninges (figure 11-7). These coverings provide protection.
Figure 11-7. A schematic diagram of the meninges, as seen in side view of the CNS.

1. **Dura mater.** The dura mater is a tough outer covering for the CNS. Beneath the dura mater is the **subdural space**, which contains a thin film of fluid.

2. **Arachnoid mater.** To the inner side of the dura mater and subdural space is a fine membranous layer called the **arachnoid mater**. It has fine spiderweb-type threads which extend inward through the **subarachnoid space** to the pia mater. The subarachnoid space is filled with cerebrospinal fluid (CSF).

   ARACHNOID = spider-like

3. **Pia mater.** The pia mater is a delicate membrane applied directly to the surface of the brain and the spinal cord. It carries a network of blood vessels to supply the nervous tissues of the CNS.

11-12. **BLOOD SUPPLY OF THE CNS**

a. **Blood Supply of the Brain.** The paired internal carotid arteries and the paired vertebral arteries supply blood rich in oxygen to the brain. Branches of these arteries join to form a circle under the base of the brain. This is called the cerebral circle (of Willis). From this circle, numerous branches supply specific areas of the brain.

   (1) A single branch is often the only blood supply to that particular area. Such an artery is called an end artery. If it fails to supply blood to that specific area, that area will die (stroke).

   (2) The veins and venous sinuses of the brain drain into the paired internal jugular veins, which carry the blood back toward the heart.

b. **Blood Supply of the Spinal Cord.** The blood supply of the spinal cord is by way of a combination of three longitudinal arteries running along its length and reinforced by segmental arteries from the sides.
11-13. CEREBROSPINAL FLUID (CSF)

A clear fluid called cerebrospinal fluid (CSF) is found in the cavities of the CNS. CSF is found in the ventricles of the brain (para 11-9d), the subarachnoid space (para 11-11b(2)), and the central canal of the spinal cord (para 11-10b(1)). CSF and its associated structures make up the circulatory system for the CNS.

a. Choroid Plexuses. Choroid plexuses are special collections of arterial capillaries found in the roofs of the third and fourth ventricles of the brain. The choroid plexuses continuously produce CSF from the plasma of the blood.

b. Path of the CSF Flow. Blood flows through the arterial capillaries of the choroid plexuses. As CSF is produced by the choroid plexuses, it flows into all four ventricles. CSF from the lateral ventricles flows into the third ventricle and then through the cerebral aqueduct into the fourth ventricle. By passing through three small holes in the roof of the fourth ventricle, CSF enters the subarachnoid space. From the subarachnoid space, the CSF is transported through the arachnoid villi (granulations) into the venous sinuses. Thus, the CSF is formed from arterial blood and returned to the venous blood.

Section IV. THE PERIPHERAL NERVOUS SYSTEM (PNS)

11-14. GENERAL

a. Definitions.

(1) The peripheral nervous system (PNS) is that portion of the nervous system generally concerned with commands for skeletal muscles and other muscles made up of striated muscle tissue, as well as sensory information from the periphery of the body. The sensory information is carried to the CNS where it is processed. The PNS carries commands from the CNS to musculature.

(2) A nerve is a collection of neuron processes, together and outside the CNS. (A fiber tract is a collection of neuron processes, together and inside the CNS.)

b. General Characteristics of the Peripheral Nerves. The PNS is made up of a large number of individual nerves. These nerves are arranged in pairs. Each pair includes one nerve on the left side of the brainstem or spinal cord and one nerve on the right side. The nerve pairs are in a series, each pair resembling the preceding, from top to bottom.

c. Categories of PNS Nerves. PNS nerves include cranial nerves and spinal nerves.
(1) Cranial nerves. The 12 pairs of nerves attached to the right and left sides of the brainstem are called cranial nerves. Each cranial nerve is identified by a Roman numeral in order from I to XII and an individual name. For example, the Vth ("fifth") cranial nerve is known as the trigeminal nerve (N.).

TRI = three
GEMINI = alike
TRIGEMINAL = having three similar major branches

(2) Spinal nerves. Attached to the sides of the spinal cord are 31 pairs of spinal nerves. The spinal nerves are named by:

(a) The region of the spinal cord with which the nerve is associated.

(b) An Arabic numeral within the region. For example, T-5 is the fifth spinal nerve in the thoracic region.

11-15. A "TYPICAL" SPINAL NERVE

In the human body, every spinal nerve has essentially the same construction and components. By learning the anatomy of one spinal nerve, you can understand the anatomy of all spinal nerves.

a. Parts of a "Typical" Spinal Nerve (figure 11-8). Like a tree, a typical spinal nerve has roots, a trunk, and branches (rami).

![Figure 11-8. A "typical" spinal nerve with a cross section of the spinal cord.](image)

MD0006 11-16
(1) Coming off of the posterior and anterior sides of the spinal cord are the posterior (dorsal) and anterior (ventral) roots of the spinal nerve. An enlargement on the posterior root is the posterior root ganglion. A ganglion is a collection of neuron cell bodies, together, outside the CNS.

(2) Laterally, the posterior and anterior roots of the spinal nerve join to form the spinal nerve trunk. The spinal nerve trunk of each spinal nerve is located in the appropriate intervertebral foramen of the vertebral column. (An intervertebral foramen is a passage formed on either side of the junction between two vertebrae.)

(3) Where the spinal nerve trunk emerges laterally from the intervertebral foramen, the trunk divides into two major branches. These branches are called the anterior (ventral) and posterior (dorsal) primary rami (ramus, singular). The posterior primary rami go to the back. The anterior primary rami go to the sides and front of the body and also to the upper and lower members.

b. Neurons of a "Typical" Spinal Nerve. A nerve is defined above as a collection of neuron processes. Thus, neuron processes are the components that make up a nerve. These processes may belong to any of several different types of neurons: afferent (sensory), efferent (motor), and visceral motor neurons of the ANS.

(1) The afferent neuron and the efferent neuron are the two types we will consider here. An afferent neuron is one which carries information from the periphery to the CNS.

\[ A = \text{toward} \]
\[ \text{FERENT} = \text{to carry} \]

An efferent neuron is one which carries information from the CNS to a muscle or gland.

\[ E = \text{away from} \]
\[ \text{FERENT} = \text{to carry} \]

(2) The afferent neuron is often called the sensory neuron because it carries information about the senses to the CNS. The efferent neuron is often called the motor neuron because it carries commands from the CNS to cause a muscle to act.

(3) A stimulus acts upon a sensory receptor organ in the skin or in another part of the body. The information is carried by an afferent (sensory) neuron through merging branches of the spinal nerve to the posterior root ganglion. The afferent (sensory) neuron's cell body is located in the posterior root ganglion. From this point, information continues in the posterior root to the spinal cord. The efferent (motor) neuron carries command information from the spinal cord to the individual muscle of the human body.
(4) Visceral motor neurons of the ANS (see section V), which innervate visceral organs of the body's periphery, are distributed along with the peripheral nerves.

c. The General Reflex Arc (figure 11-9).

![Diagram of the general reflex arc]

Figure 11-9. The general reflex arc.

1. Definitions.

(a) An automatic reaction to a stimulus (without first having conscious sensation) is referred to as a reflex. (As an example: The withdrawal of the hand from a hot object.)

(b) The pathway from the receptor organ to the reacting muscle is called the reflex arc.

2. Components of the general reflex arc. The pathway of a general reflex arc involves a minimum of five structures.

(a) The stimulus is received by a receptor organ.

(b) That information is transmitted to the CNS by the afferent (sensory) neuron.
(c) Within the spinal cord, there is a special neuron connecting the afferent neuron to the efferent neuron. This special connecting neuron is called the internuncial neuron, or interneuron.

\[\text{INTER} = \text{between}\]

\[\text{NUNCIA} = \text{messenger}\]

\[\text{INTERNUNCIAL} = \text{the carrier of information between}\]

(d) The efferent (motor) neuron carries the appropriate command from the spinal cord to the reacting muscle.

(e) The reacting muscle is called the effector organ.

Section V. THE AUTONOMIC NERVOUS SYSTEM (ANS)

11-16. GENERAL

The autonomic nervous system (ANS) is that portion of the nervous system generally concerned with commands for smooth muscle tissue, cardiac muscle tissue, and glands.

a. Visceral Organs.

(1) Definition. The term visceral organs may be used to include:

(a) The various hollow organs of the body whose walls have smooth muscle tissue in them. Examples are the blood vessels and the gut.

(b) The glands.

(2) Distribution. The visceral organs are located in the central cavity of the body (example: stomach) and throughout the periphery of the body (example: sweat glands of the skin).

(3) Control. It has always been thought that the control of visceral organs was "automatic" and not conscious. However, recent researches indicate that proper training enables a person to consciously control some of the visceral organs.

b. Efferent Pathways. Earlier, we said that each neuron in the PNS extended the entire distance from the CNS to the receptor or effector organ. In the ANS, there are always two neurons (one after the other) connecting the CNS with the visceral
organ. The cell bodies of the second neurons form a collection outside the CNS, called a ganglion.

(1) The first neuron extends from the CNS to the ganglion and is therefore called the preganglionic neuron.

(2) Cell bodies of the second neuron make up the ganglion. The second neuron’s processes extend from the ganglion to the visceral organ. Thus, the second neuron is called the post-ganglionic neuron.

c. **Major Divisions of the Human ANS.** The efferent pathways of the ANS fall into two major divisions:

   (1) The thoraco-lumbar outflow (sympathetic nervous system).

   (2) The cranio-sacral outflow (parasympathetic nervous system).

d. **Major Activities of the Human ANS.**

   (1) The ANS maintains visceral activities in a balanced or stable state. This is called homeostasis.

   (2) When subjected to stress, such as a threat, the body responds with the "fight-or-flight reaction." That is, those activities of the body necessary for action in an emergency are activated and those not necessary are deactivated. This is the primary function of the sympathetic portion of the ANS.

### 11-17. THE THORACO-LUMBAR OUTFLOW (SYMPATHETIC NERVOUS SYSTEM)

a. Refer to paragraph 11-10b(2) which describes the H-shaped region of gray matter in the cross section of the spinal cord. Imagine extending the cross link of the H slightly to the left and right of the vertical arms; the extended ends would correspond to the intermediolateral gray columns. Cell bodies of the first neurons of the sympathetic NS make up those columns between the T-1 and L-2 levels of the spinal cord, a total of 14 levels. Here, we are speaking of preganglionic sympathetic neurons.

b. Cell bodies of the second neurons make up various sympathetic ganglia of the body. These ganglia include the trunk or chain ganglia and the pre-aortic or "central" ganglia. Here, we are speaking of post-ganglionic sympathetic neurons.

c. The sympathetic NS innervates:

   (1) Peripheral visceral organs (example: sweat glands).

   (2) Central visceral organs (examples: lungs and stomach).
d. The neurons innervating the peripheral visceral organs are distributed to them by being included in the nerves of the PNS.

e. The sympathetic NS activates those visceral organs needed to mobilize energy for action (example: heart) and deactivates those not needed (example: gut).

11-18. THE CRANIO-SACRAL OUTFLOW (PARASYMPATHETIC NERVOUS SYSTEM)

a. Cell bodies of the first neurons of the parasympathetic NS make up the intermediolateral gray columns in the sacral spinal cord at the S-2, S-3, and S-4 levels. See paragraph 11-17a above for the position of the intermediolateral gray columns. Cell bodies of the first neurons also make up four pairs of nuclei in the brainstem; these nuclei are associated with cranial nerves III, VII, IX, and X. Here, we are speaking of preganglionic parasympathetic neurons.

b. Cell bodies of the second neurons make up intramural ganglia within the walls of the visceral organs. These second neurons innervate the central visceral organs. They do NOT innervate peripheral visceral organs. Here, we are speaking of the post-ganglionic parasympathetic neurons.

c. The parasympathetic NS has the opposite effect on visceral organs from that of the sympathetic NS. (Example: The heart is accelerated by the sympathetic NS and decelerated by the parasympathetic NS.)

Section VI. PATHWAYS OF THE HUMAN NERVOUS SYSTEM

11-19. GENERAL

a. Definitions.

(1) A pathway is the series of nervous structures utilized in the transmission of an item of information. An example of a pathway is the reflex arc discussed in paragraph 11-15c.

(2) The brainstem is continuous with the spinal cord. Together, the brainstem and the spinal cord are sometimes known as the neuraxis.

b. General Categories of Neural Pathways.

(1) Sensory pathways. A sensory pathway is a series of nervous structures used to transmit information from the body to the CNS. Upon arrival in the CNS, these pathways ascend (go up) the neuraxis to the brain.
(2) **Motor pathways.** A motor pathway is a series of nervous structures used to transmit information from the CNS to the body. The commands for motor action originate in the brain and descend (go down) the neuraxis to the appropriate spinal levels. From this point, the commands pass through the nerves to the effector organs.

c. **Controls.** The human nervous system has several levels for control. The lowest level is the simple reflex arc (see para 11-15c). The highest level of control is the conscious level. From the lowest to the highest levels are several progressively higher levels, such as the righting reflex. Thus, the processing of information and the transmission of commands are not haphazard but very carefully monitored and controlled. All information input and all information output are monitored and evaluated.

11-20. **THE MOTOR PATHWAYS**

Motor pathways begin in the brain. They descend the neuraxis in bundles of a number of specific neuron processes called motor fiber tracts. Commands originating in the right half of the brain leave the CNS through peripheral nerves on the left side. Commands from the left half of the brain leave the CNS on the right side. Therefore, the right half of the brain controls the left side of the body and the left half of the brain controls the right side of the body. For example, the actions of the right hand are controlled by the left half of the brain. (In those people who are right-handed, we refer to the left half of the brain as being dominant.)

a. **Pyramidal Motor Pathways.** A pyramidal motor pathway is primarily concerned with volitional (voluntary) control of the body parts, in particular the fine movements of the hands. Because control is volitional, the pathways can be used for neurological screening and testing. These pathways are called pyramidal because their neuron processes contribute to the makeup of a pair of structures in the base of the brain known as the pyramids.

b. **Extrapyramidal Motor Pathways.** An extrapyramidal pathway is primarily concerned with automatic (nonvolitional) control of body parts for purposes of coordination. Extrapyramidal pathways use many intermediate relays before reaching the effector organs. The cerebellum of the brain plays a major role in extrapyramidal pathways; the cerebellum helps to integrate patterned movements of the body.

11-21. **THE SENSORY PATHWAYS**

a. The body is continuously bombarded by types of information called stimuli (stimulus, singular). Those few stimuli which are consciously perceived (in the cerebral hemispheres) are called sensations.

b. Those stimuli received throughout the body are called the general senses. Stimuli received by only single pairs of organs in the head (for example, the eyes) are called special senses (for example, smell and taste).
c. The general senses in humans include pain, temperature (warm and cold), touch (light and deep), and proprioception ("body sense": posture, tone, tension).

d. The special senses in humans include smell (olfaction), taste (gustation), vision, hearing (auditory), and equilibrium.

e. The input from each special sensory receptor goes to its own specific area of the opposite cerebral hemisphere. The general sensory pathway is from the receptor organ, via the PNS nerves, to the CNS. This general pathway then ascends fiber tracts in the neuraxis. The pathway ends in the central area of the cerebral hemisphere (on the side opposite to the input).

Section VII. THE SPECIAL SENSE OF SMELL (OLFACTION)

11-22. SENSORY RECEPTORS

Molecules of various materials are dispersed (spread) throughout the air we breathe. A special olfactory epithelium is located in the upper recesses of the nasal chambers in the head. Special hair cells in the olfactory epithelium are called chemoreceptors, because they receive these molecules in the air.

11-23. OLFATORY SENSORY PATHWAY

The information received by the olfactory hair cells is transmitted by way of the olfactory nerves (cranial nerves I). It passes through these nerves to the olfactory bulbs and then into the opposite cerebral hemisphere. Here, the information becomes the sensation of smell.

Section VIII. THE SPECIAL SENSE OF TASTE (GUSTATION)

11-24. SENSORY RECEPTORS

Molecules of various materials are also dispersed or dissolved in the fluids (saliva) of the mouth. These molecules are from the food ingested (taken in). Organs known as taste buds are scattered over the tongue and the rear of the mouth. Special hair cells in the taste buds are chemoreceptors to react to these molecules.

11-25. SENSORY PATHWAY

The information received by the hair cells of the taste buds is transmitted to the opposite side of the brain by way of three cranial nerves (VII, IX, and X). This information is interpreted by the cerebral hemispheres as the sensation of taste.
Section IX. THE SPECIAL SENSE OF VISION (SIGHT)

11-26. GENERAL

a. **Stimulus.** Rays of light stimulate the receptor tissues of the eyeballs (bulbus oculi) to produce the special sense of vision. This includes both the sensation of vision or seeing and a variety of reactions known as the light reflexes. The actual reception of the light energy is a chemical reaction which in turn stimulates the neuron endings.

b. **Optical Physics.** To appreciate the functioning of the bulbus oculi, some simple principles of optical physics must be understood.

   (1) By means of a lens system, light rays are bent and brought to the focal point for acute vision. This process is referred to as focusing.

   (2) The focal length is the distance from the focal point to the center of the lens. The amount of bending or focusing depends upon the exact curvatures of the lens system.

c. **Sense Organ.** The eyeball is the special sense organ which contains the receptor tissues. The eyeball is suspended in the orbit. The orbit is a skeletal socket of the skull which helps protect the eyeball. Various structures associated with the functioning of the eyeball are called the adnexa. The adnexa include the eyelids, the lacrimal system, etc.

11-27. THE EYEBALL (FIGURE 11-10)

a. **Shape.** In the main, the eyeball is a spherical bulb-like structure. Its anterior surface, transparent and more curved, is known as the cornea of the eyeball.

b. **Wall of the Eyeball.** The eyeball is a hollow structure. Its wall is made up of three layers known as coats or tunics.

   (1) **Sclera.** The outermost layer is white and very dense FCT (fibrous connective tissue). It is known as the sclera, scleral coat, or fibrous tunic. Its anterior portion is called the cornea. As already mentioned, the cornea is transparent and more curved than the rest of the sclera. The fixed curvature of the cornea enables it to serve as the major focusing device for the eyeball.

   (2) **Choroid.** The middle layer of the wall of the eyeball is known as the choroid, the choroid coat, or the vascular tunic. This layer is richly supplied with blood vessels. It is also pigmented with a black material. The black color absorbs light rays and prevents them from reflecting at random.
Figure 11-10. A horizontal section of the eyeball.

(3) Retina. The inner layer of the wall of the eyeball is known as the retina, retinal coat, or internal tunic. The actual photoreceptor elements are located in the retina at the back and sides of the eyeball. These elements are the rods and cones. They constitute the nervous portion of the retina. In the anterior part of the eyeball, the retina continues as a nonnervous portion.
c. **Internal Structures of the Eyeball.**

(1) The nervous retina.

(a) The photoreceptors of the nervous portion of the retina (figure 11-11) contain chemicals known as visual pigments (rhodopsin). The cones are more concentrated in the center at the back of the eyeball. The cones can register colors and are used for acute vision. However, cones require more intense light than do rods. The rods are distributed more toward the sides of the nervous retina. Although the rods are capable of registering less intense light, rods perceive only black and white.

![Cellular detail of the retina.](image)

Figure 11-11. Cellular detail of the retina.
(b) If you look directly at an object, light from the object will fall in a small depression of the retina called the **fovea centralis**. The fovea centralis is at the posterior end of the **eyeball**, exactly opposite the centers of the cornea, pupil, and lens. The fovea centralis is found in a small yellow area of the retina called the **macula lutea**. The macula lutea is the area of the retina where vision is sharpest.

**FOVEA** = small depression  
**CENTRALIS** = center  
**MACULA** = spot  
**LUTEA** = yellow  

(c) Associated with the rods and cones are the beginnings of neurons of the optic nerve. These neurons pass out of the eyeball at the posterior end (in a point medial and superior to the fovea centralis). At the point of exit, there are no rods or cones. Therefore, it is called the **blind spot** (optic disc).

(2) **Ciliary body.** The anterior end of the choroid layer thickens to form a circular "picture frame" around the lens of the eyeball. This is also near the margin of the base of the cornea. The framelike structure is called the **ciliary body**. It includes mostly radial muscle fibers, which form the **ciliary muscle**.

(3) **Ligaments.** The lens is suspended in place by ligaments (fibers of the **ciliary zonule**). These ligaments connect the margin (equator) of the lens with the ciliary body.

(4) **Lens.** The lens is located in the center of the anterior of the eyeball, just behind the cornea.

(a) The lens is biconvex. This means that it has two outwardly curved surfaces. The anterior surface is flatter (less curved) than the posterior surface.

(b) The lens is transparent and elastic. (As one grows older, the lens becomes less and less elastic.) The ligaments maintain a tension upon the lens. This tension keeps the lens flatter and allows the lens to focus on distant objects. When the ciliary muscle contracts, the tension on the lens is decreased. The decreased tension allows the lens to thicken. The greater thickness increases the anterior curvature and allows close objects to be seen clearly.

(c) The process of focusing the lens for viewing close objects clearly is called **accommodation**. The process of accommodation is accompanied by a reduction in the pupil size as well as a convergence of the two central lines of sight (axes of eyeball).
(5) **Iris.** Another structure formed from the anterior portion of the choroid layer is the iris. The iris is located between the lens and the cornea.

(a) The **pupil** is the hole in the middle of the iris. The size of the pupil is controlled by radial and circular muscles in the iris. The radial muscles are dilators. The circular muscles are constrictors. By changing the size of the pupil, the iris controls the amount of light entering the eyeball.

(b) The iris may have many different colors. The actual color is determined by multiple genes.

(6) **Chambers.** The space between the cornea and the lens is called the anterior cavity. The space between the cornea and the iris is called the anterior chamber. The space between the iris and the lens is called the posterior chamber (see fig 11-10). Both chambers of the anterior cavity are filled with a fluid called the aqueous humor. The aqueous humor is secreted into the chambers by the ciliary body. It drains into the encircling canal of Schlemm, located in the angle between the cornea and the iris. This angle is called the iridocornealis angle.

(7) **Vitreous body.** Behind the lens is a jellylike material called the vitreous body.

### 11-28. THE ORBIT

The **orbit** is the cavity in the upper facial skull which contains the eyeball and its adnexa. The orbit is open anteriorly.

a. The floor of the orbit is generally horizontal. Its medial wall is generally vertical and straight from front to back. Since the lateral wall and roof converge to the rear, the orbit is a conelike cavity.

b. In the facial skull, the orbit is surrounded by a number of specific spaces. Superiorly, the roof of the orbit is also the floor of the anterior cranial cavity, where the frontal portion of the brain is. Just medial to the medial wall are the structures of the nasal chamber. Inferiorly, the floor of the orbit is also the roof of the maxillary sinus. Laterally, the wall of the orbit is the inner wall of the temporal fossa, a depression on each side of the skull where a fan-shaped chewing muscle (temporalis M.) is attached.

### 11-29. THE ADNEXA

The adnexa are the various structures associated with the eyeball.

a. **Extrinsic Ocular Muscles.** Among the adnexa are the extrinsic ocular muscles, which move the eyeball within the orbit. Each eyeball has associated with it six muscles made up of striated muscle fibers.
(1) **Four recti.** Four of these muscles are straight from the rear of the orbit to the eyeball. They are therefore known as the *recti* muscles (RECTUS = straight). Each name indicates the position of the muscles in relationship to the eyeball as follows:

- lateral rectus M. (on the outer side)
- superior rectus M. (above)
- medial rectus M. (on the inner side)
- inferior rectus M. (below)

(2) **Two obliques.** Two muscles approach the eyeball from the medial side and are known as the *superior oblique* and *inferior oblique* muscles.

b. **Eyelids.** Attached to the margins of the orbit, in front of the eyeball, are the upper and lower eyelids (palpebra (Latin), blepharon (Greek)). These have muscles for opening and closing the eyelids. The eyelashes (cilia) are special hairs of the eyelids which help protect the eyeball. The margins of the eyelids have special oil to prevent the loss of fluids from the area. The inner lining of the eyelids is continuous with the conjunctiva, a membrane over the anterior surface of the eyeball.

c. **Lacrimal Apparatus.** The conjunctiva must be kept moist and clean at all times. To do this, a lacrimal apparatus is associated with the eyelids. In the upper outer corner of the orbit is a *lacrimal gland*, which secretes a *lacrimal fluid* (tears) into the junction between the upper eyelid and the conjunctiva. By the motion of the eyeball and the eyelids (blinking), this fluid is moved across the surface of the conjunctiva to the medial inferior aspect. Here, the lacrimal fluid is collected and delivered into the nasal chamber by the *nasolacrimal duct*.

d. **Eyebrow.** The eyebrow (supercilium) is a special group of hairs above the orbit. The eyebrow serves to keep rain and sweat away from the eyeball.

e. **Optic Nerve (Cranial Nerve II).** Neurons carry information from the photoreceptors of the nervous retina. They leave the eyeball at the blind spot. At the optic nerve, or second cranial nerve, the neurons pass to the rear of the orbit. There, the optic nerve exits through the *optic canal* into the cranial cavity. Beneath the brain, the optic nerves from both sides join to form the *optic chiasma*, in which half of the neurons from each optic nerve cross to the opposite side. From the optic chiasma, the right and left optic tracts proceed to the brain proper.
Section X. THE SPECIAL SENSE OF HEARING (AUDITORY)

11-30. GENERAL

The human ear serves two major special sensory functions--hearing (auditory) and equilibrium (balance). The stimulus for hearing is sound waves. The stimulus for equilibrium is gravitational forces.

a. Methods of Sound Transmission. The sound stimulus is transmitted in a variety of ways. Regardless of the actual transmission method, the sound stimulus is unchanged. Sound may be transmitted as:

(1) **Airborne waves.** These airborne waves have frequency (pitch) and amplitude (loudness or intensity).

(2) **Mechanical oscillations (vibrations) of structures.**

(3) **Fluid-borne pressure pulses.**

(4) **Electrical impulses** along the neurons to and in the brain.

b. Sections of the Human Ear (figure 11-12). The human ear has three major parts. Each part serves a specific function in the transmission and reception of the sound stimulus. The three parts are known as the external (outer) ear, the middle ear, and the internal (inner) ear.

11-31. THE EXTERNAL EAR

The external ear begins on the outside of the head in the form of a funnel-shaped **auricle (pinna).** Actually serving as a funnel, the auricle directs airborne sound waves into the external auditory meatus. The external **auditory meatus** is a tubular canal extending into the temporal portion of the skull.

11-32. THE MIDDLE EAR

a. **Tympanic Membrane.** At the inner end of the external auditory meatus is the tympanic membrane. The **tympanic membrane** (eardrum) is a circular membrane separating the external auditory meatus from the middle ear cavity. The tympanic membrane vibrates (mechanically oscillates) in response to airborne sound waves.

b. **Middle Ear Cavity.** On the medial side of the tympanic membrane is the middle ear cavity. The **middle ear cavity** is a space within the temporal bone.
c. **Auditory Ossicles.** The auditory ossicles (OSSICLE = small bone) are three very small bones which form a chain across the middle ear cavity. They join the tympanic membrane with the medial wall of the middle ear cavity. In order, the ossicles are named as follows: malleus, incus, and stapes. The malleus is attached to the tympanic membrane. A sound stimulus is transmitted from the tympanic membrane to the medial wall of the middle ear cavity by way of the ossicles. The ossicles vibrate (mechanically oscillate) in response to the sound stimulus.

d. **Auditory (Eustachian) Tube.** The auditory tube is a passage connecting the middle ear cavity with the nasopharynx. The auditory tube maintains equal air pressure on the two sides of the tympanic membrane.

e. **Association With Other Spaces.** The middle ear cavity is associated with other spaces in the skull. The thin roof of the middle ear cavity is the floor of part of the cranial cavity. The middle ear cavity is continuous posteriorly with the mastoid air cells via the antrum (an upper posterior recess of the middle ear cavity).
11-33. THE INTERNAL EAR

a. Labyrinths (Figure 11-13).

Figure 11-13. The labyrinths of the internal ear.

(1) Bony labyrinth. The bony labyrinth (LABYRINTH = a maze) is a complex cavity within the temporal bone. It has three semicircular canals, a vestibule (hallway), and a snail-shaped cochlear portion.

(2) Membranous labyrinth. The membranous labyrinth is a hollow tubular structure suspended within the bony labyrinth.

b. Fluids of the Internal Ear. The endolymph is a fluid filling the space within the membranous labyrinth. The perilymph is a fluid filling the space between the membranous labyrinth and the bony labyrinth. These fluids are continuously formed and drained away.

ENDO = within
PERI = around
c. The Cochlea. The cochlea is a spiral structure associated with hearing. It has 2-1/2 turns. Its outer boundaries are formed by the snail-shaped portion of the bony labyrinth.

(1) The central column or axis of the cochlea is called the modiolus. Extending from this central column is a spiral shelf of bone called the spiral lamina. A fibrous membrane called the basilar membrane (or basilar lamina) connects the spiral lamina with the outer bony wall of the cochlea. The basilar membrane forms the floor of the cochlear duct, the spiral portion of the membranous labyrinth. Within the cochlear duct, there is a structure on the basilar membrane called the organ of Corti. The organ of Corti has hairs which are the sensory receptors for the special sense of hearing.

LAMINA = thin plate

(2) Within the bony cochlea, the space above the cochlear duct is known as the scala vestibuli and the space below is known as the scala tympani. (See figure 11-14.) Since the scalae are joined at their apex, they form a continuous channel and the connection between them is called the helicotrema.

(3) Between the scalae and the middle ear cavity are two windows.

(a) Fenestra vestibuli (oval window). Between the middle ear cavity and the scala vestibuli is an oval window called the fenestra vestibuli. It is filled with the foot plate of the stapes.

(b) Fenestra cochleae (round window). Between the middle ear cavity and the scala tympani is a round window called the fenestra cochleae. It is covered or closed by a membrane.

d. Transmission.

(1) The sound stimulus is transferred from the stapes to the perilymph of the scala vestibuli. Here the stimulus is transmitted as a pressure pulse in the fluid.

(2) In response, the basilar membrane of the cochlea vibrates (mechanically oscillates). Only selected portions of the basilar membrane vibrate at any one time, depending on the frequency of the sound stimulus.

(3) The hair cells of the organ of Corti at that particular location are mechanically stimulated. This stimulation is transferred to the neurons of the acoustic nerve (cranial nerve VIIIa). The acoustic nerve passes out of the modiolus into the internal auditory meatus of the temporal bone. From here, it enters into the cranial cavity and goes to the brain.
Figure 11-14. Diagram of the scalae.
Section XI. THE SPECIAL SENSE OF EQUILIBRIUM (BALANCE)

11-34. GENERAL

a. **Posture.** Posture is the specific alinement of the body parts at any given time. Humans can assume an infinite variety of postures. However, the truly erect posture is unique to humans.

b. **Equilibrium.** Equilibrium is the state of balance of the body. An erect standing human has a highly unstable equilibrium and therefore can easily fall. Through a variety of sensory inputs (visual, etc.) and postural reflexes, the body is maintained in its erect posture.

c. **Stimulus-Gravitational Forces.** A primary sensory input for equilibrium consists of gravitational forces. This input is received by the membranous labyrinth within the internal ear. The gravitational forces are of two types: static, when the body is standing still, and kinetic, when the body is moving in either linear (straight) or angular directions.

d. **Membranous Labyrinth.** The specific portions of the membranous labyrinth involved are the two sac-like structures—the sacculus and the utriculus. Each of these two structures has an area of special hair cells called the macula. In addition, there are three semicircular ducts located within the osseous semicircular canals of the temporal bone of the skull. Each semicircular duct has a crista, a little ridge of hair cells across the axis of the duct.

e. "**Body Sense.**" All of the various sensory inputs related to the maintenance of equilibrium and posture are integrated within the brain as "body sense." Correct information is sent to the muscles of the body by means of specific postural reflexes in order to maintain the proper posture.

11-35. SACCUS AND UTRICULUS

a. The sacculus and the utriculus are two sac-like portions of the membranous labyrinth. They are filled with endolymph.

b. On the wall of each sac is a collection of special hair cells known as the macula, which serves as a receptor organ for static and linear kinetic gravitational forces. The saccular macula and the utricular macula are oriented at more or less right angles to each other. For the pair of maculae in the membranous labyrinth of the right side, there is a corresponding pair in the labyrinth of the left side. Information from all of these maculae is sent into the brain for continuous sensing of the position of the head in space.
11-36. SEMICIRCULAR DUCTS (FIGURE 11-15)

Extending from and opening into the utriculus are three hollow structures called the semicircular ducts. Since the utriculus completes the circle for each duct, the ducts act as if they were complete circles.

Figure 11-15. Diagram of semicircular duct orientation.

a. Orientation. Two of the ducts are vertically oriented (one anterior and one posterior). The third duct is essentially horizontal. The three ducts are all oriented at right angles to each other. In addition, the three ducts of one membranous labyrinth are matched or paired by the three ducts of the opposite membranous labyrinth.

b. Ampullae and Cristae. Each semicircular duct ends with an enlargement where it opens into the utriculus. This enlargement or swelling is called an ampulla. The crista is at a right angle to the axis of the duct. Movement of the endolymph within the duct—caused by movement of the head in space—deforms (bends) the hairs of the crista in specific directions. These are responses to linear and/or angular kinetic gravitational forces.
11-37. THE VESTIBULAR NERVE

The vestibular nerve (cranial nerve VIII) carries all this information from the maculae and cristae to the brain. The vestibular and auditory nerves are contained in the same fibrous sheath from the membranous labyrinth to the brain. Within the brain, the vestibular and auditory nerves separate into different pathways.

Section XII. CONTROLS IN THE HUMAN NERVOUS SYSTEM

11-38. GENERAL CONCEPT

The human nervous system can be thought of as a series of steps or levels. Each level is more complex than the level just below. No level is completely overlapped by upper levels, but each level is controlled or guided by the next upper level as it functions.

11-39. LEVELS OF CONTROL

a. Reflex Arc. The simplest and lowest level of control is the reflex arc (see para 11-15c). The reflex arc operates essentially on the level of the sensory input.

b. Segmental Reflexes. Segmental reflexes produce a wider reaction to a stimulus than the reflex arc. For this purpose, the nervous system is organized more complexly. Thus, information spreads to a wider area of the CNS. We can observe a greater reaction to the stimulus.

c. Medullary Hindbrain. In the hindbrainstem are to be found a number of nuclei (collections of neuron cell bodies) which monitor and control the activities of the visceral functions of the body, such as respiration, heartbeat, etc.

d. Reticular Formation. Within the substance of the brainstem is a diffuse system called the reticular formation.

RETICULAR = network

This reticular formation has a facilitatory (excitatory) area and an inhibitory area. These areas monitor and control general body functions, including sleep.

e. Thalamus. In the forebrainstem is a major collection of nuclei, all together called the thalamus. The thalamus is a primary relay for information going to and from the cerebrum and cerebellum. In the lowest animals, the thalamus represents the highest level of nervous control.
f. **Cerebellum.** The cerebellum has been greatly developed with many functional subdivisions. All together, it is one of the most important integrators of motor activity of the body.

g. **Cerebrum.** In humans, the highest level of nervous control is localized in the cerebrum. It is at this level that conscious sensation and volitional motor activity are localized. Even so, we can clearly designate three levels of control within the cerebrum:

1. **Visceral (vegetative) level.** This level is concerned primarily with visceral activities of the body as related to fight-or-flight, fear, and other emotions.

2. **Patterned (stereotyped) motor actions.** Here, activities of the body are standardized and repetitive in nature. An example of a stereotyped pattern of muscle activity would be the sequence of muscle actions involved in walking.

3. **Volitional level.** The volitional level is the highest and newest level of control. Here, unique, brand-new solutions can be created.
EXERCISES, LESSON 11

REQUIREMENT. The following exercises are to be answered by completing the incomplete statement or by writing the answer in the space provided at the end of the question.

After you have completed all the exercises, turn to "Solutions to Exercises," at the end of the lesson and check your answers.

1. Two types of nervous tissues are ________________ and ________________.
   What role does the first play in the nervous system?

   What role does the second play?

2. Nervous tissues are specialized to:
   a. _______ stimuli.
   b. _______ information.
   c. _______ information.

3. A neuron is a nerve cell body and all of its ____________s.

4. A dendrite carries impulses (toward) (away from) the cell body.

5. What is an axon?

6. Each item below indicates the number of poles for a type of neuron. Give the name which corresponds to each.
   a. More than two poles: ____________.
   b. Two poles: _________________.
   c. One pole: _________________.

MD0006

11-39
7. Each item below refers to the thickness of the myelin surrounding an axon. Give the letter indicating the type of neuron.
   a. Thickest: ______________________.
   b. Medium: ______________________.
   c. Thinnest: ______________________.

8. Each item below indicates the route over which impulses are transmitted. Give the type of neuron corresponding to each route.
   a. From receptor organs to the CNS: __________.
   b. From the CNS to muscles and glands: __________.
   c. From one neuron to another: __________.

9. What is meant by the term "continuity without contact" as related to neuron "connections"?

10. What is a synapse?

    An axon terminates in tiny branches. What is at the end of each branch?

    Where is neurotransmitter stored?

    What is the presynaptic membrane?

    What is the synaptic cleft?

    What is the postsynaptic membrane?
11. What is a neuromuscular junction?

Compare the neuromuscular junction to a synapse.

12. The major divisions of the human nervous system are the__________ nervous system (_____), the __________ nervous system (_____), and the __________ nervous system (______). The CNS is made up of the ____ and the ______ ______.

13. The three major subdivisions of the human brain are the______________, the __________, and the __________.

What is the brainstem?

14. The cerebellum is a spherical mass of nervous tissue attached to and covering the ____________. Its three major parts are the ___________ and right and left ___________ hemispheres. In addition, the cerebellum has three pairs of stem-like connecting parts called ___________. The outer cortex is composed of ___________ matter, which is the ___________ of neurons. More central is the ___________ matter, which is the myelinated processes of ___________. The cerebellum is the primary ___________/__________ of motor actions of the body.

15. The cerebrum consists of two very much enlarged ____________ s connected to each other by a special structure called the c________ c__________. Each cerebral hemisphere is connected to the brainstem by a c________ p________. The surface of each cerebral hemisphere is subdivided into areas known as l_______. The names of the four lobes are f_______, p_______, o_______, and t_______.

16. The space separating the two cerebral hemispheres is called the longitudinal ___________. The shallow grooves in the surface of the cerebrum are called ___________. The ridges outlined by the grooves are called ______.

17. The gray outer layer of each hemisphere is the __________ ___________. Deeper within the cerebral hemispheres, the tissue is colored _______. The "gray matter" represents the _______ _______s of the neurons. The "white matter" represents the _____________.
18. Groups of related functions are associated with specific areas of the cerebral cortex. For example, centers of speech and hearing are located along the lateral _______. Vision is centered in the _______ lobe. Sensory and motor functions are located along the central_______.

19. The ventricles of the brain are interconnected hollow spaces filled with ______. The right and left lateral ventricles are found in the cerebral __________s. The lateral ventricles are connected to the third ventricle by the i________ f________. The third ventricle is located in the f____________. The third and fourth ventricles are connected by the c__________ a__________. The fourth ventricle is located in the h__________. The fourth ventricle is continuous with the part of the spinal cord known as the c__________ c________.

20. The spinal cord, located within the spinal _______ l, is continuous with the b__________. The spinal cord has two enlargements. One, associated with nerves for the upper members, is called the __________ enlargement. The other, associated with the nerves for the lower members, is called the __________ enlargement. Nerves arising from the spinal cord are called _______ nerves.

There are how many pairs of spinal nerves?

21. In the cross section of the spinal cord, one can see a central region of gray matter shaped like an ______. Each arm of this figure is called a _____________. The connecting link is called the gray _____________. These horns are actually sections of the gray _________ s. Since a column of white matter is a large bundle of processes, it is called a _____________.

22. The skeletal covering for the brain is provided by bones of the _______. The overall skeletal structure covering the spinal cord is the _______ column (spine).

23. The brain and spinal cord have three different membranes surrounding them called _____________. The tough outer covering for the CNS is the _______. Beneath it is the ______ space. The fine second membrane is called the _____________. Beneath it is the ____ space, which is filled with ________. The delicate membrane applied directly to the surface of the brain and spinal cord is called the _____________.

MD0006 11-42
24. The two main pairs of arteries supply oxygenated blood to the brain are the internal ________ and ________ arteries. Beneath the brain, branches of these arteries join to form a circle, called the ________ circle (of __________). The main pair of veins carrying blood back toward the heart is the internal ________ veins. The blood supply of the spinal cord is by way of a combination of three l__________ arteries running along its length and reinforced by s__________ arteries from the sides.

25. Found in the cavities of the CNS is a clear fluid called_______ fluid (____). This fluid is found in the __________ s of the brain, the sub_______ space, and the spinal cord's ________ canal. Special collections of arterial capillaries found in the roofs of the third and fourth ventricles are called choroid ________s. These structures continuously produce CSF from the _________ of the blood.

26. As CSF is produced by the choroid plexuses, it flows into all four ________s. CSF from the lateral ventricles flows into the ________ ventricle, and then through the ________ aqueduct into the ________ ventricle. By passing through three small holes in the roof of the fourth ventricle, CSF enters the subarachnoid _________. From here, the CSF is transported through the arachnoid ________ into the venous sinuses.

27. The peripheral nervous system is that portion of the nervous system which generally provides commands for __________ muscles and other ________ muscles and carries ________ information from the p__________ of the body. A nerve is a collection of neuron ________ s, together and ________ the CNS.

28. The 12 pairs of nerves attached to the right and left sides of the brainstem are called ________ nerves. Each such nerve is identified by a ________ in order from ______ to ______ and an individual name. Attached to the sides of the spinal cord are 31 pairs of ________ nerves. For each, the region is designated by a ________; within each region, a nerve pair is identified by an ________________.

29. Like a tree, a typical spinal nerve has ________ s, a ____, and branches (called ________). Coming off of the posterior and anterior sides of the spinal cord are the posterior and anterior ____ of the spinal nerve. An enlargement on the posterior root is the _________. A ganglion is a collection of __________________, together, outside the CNS. Laterally, the posterior and anterior roots of the spinal nerve join to form the spinal nerve ________. The spinal nerve trunk of each spinal nerve is located in the corresponding intervertebral ________ of the vertebral column. As the nerve trunk emerges laterally, it divides into the anterior and posterior ____.
30. If it carries information from the periphery to the CNS, it is an _______ t (_______) neuron. If it carries information from the CNS to a muscle or gland, it is an _________ t (_______) neuron.

31. An automatic reaction to a stimulus is referred to as a _________. The pathway from the receptor organ to the reacting muscle is called the _________ _.

32. The pathway of a general reflex arc involves a minimum of _____ structures. The stimulus is received by a ___________ organ. That information is transmitted to the CNS by the _______ t (_______) neuron. Within the spinal cord, there is a special neuron connecting the afferent neuron to the efferent neuron; this special connecting neuron is called the _____________. Carrying the appropriate command from the spinal cord to the reacting muscle is the _______ t (_______) neuron. The reacting muscle is called the e_______ organ.

33. The autonomic nervous system is that portion of the nervous system generally concerned with commands for s________ muscle, c_______ muscles, and _________s.

34. In the ANS, the number of neurons connecting the CNS with a visceral organ is always ______. The cell bodies of the second neuron form a collection outside the CNS, called a _____________. The first neuron extends from the CNS to the ganglion and is therefore called the _____________ neuron. Cell bodies of the second neurons make up the _______. The second neuron's processes extend from the ganglion to the _________________. Thus, the second neuron is called the ___________________ neuron.

35. The efferent pathways of the ANS fall into two major divisions. The one most active during a "fight-or-flight" reaction is the ______-____ outflow (_______ nervous system). The other is the ___-_____ outflow (____________ nervous system).

36. The intermediolateral gray columns from the T-1 to the L-2 levels of the spinal cord are made up of the cell bodies of the ____-ganglionic sympathetic neurons. The sympathetic ganglia are made up of the cell bodies of the ____-ganglionic sympathetic neurons. The sympathetic NS activates those visceral organs needed to ____________________________. It deactivates those which are ________.
37. Four pairs of nuclei in the brainstem and the intermediolateral gray columns at the S-2 through S-4 levels of the spinal cord are made up of the cell bodies of the p_________ p_________ neurons. The intramural ganglia within the walls of the __________________ organs are made up of the cell bodies of the p_________ p_________ neurons. As compared to that of the sympathetic NS, the parasympathetic NS has the (same) (opposite) effect on visceral organs.

38. What is a pathway?

39. What is the neuraxis?

40. What is a sensory pathway?

41. What is a motor pathway?

42. The human nervous system has several levels of control. The lowest level is the _______ _______ ______. The highest level is the _______ level. Between, there are several progressively ______ levels. All information input and all information output are _______d and _______d.

43. The right half of the brain controls the _____ side of the body. The left half of the brain controls the _____ side of the body.

44. A pyramidal pathway is primarily concerned with ________ (________) control of body parts, particularly the ____ movements of ____s. These pathways are called pyramidal because their neuron processes help to make up structures in the base of the brain called ________.

45. An extrapyramidal pathway is primarily concerned with ________ (________) control of body parts for purposes of ______________. 
46. Name examples of general senses.
   a.  
   b.  
   c.  
   d.  

47. Name examples of special senses.
   a.  
   b.  
   c.  
   d.  
   e.  

48. The general sensory pathway is from the ______ organ, via the ___ nerves, to the ___. This general pathway then ascends fiber tracts in the ______. The pathway ends in the central area of the opposite ______ hemisphere.

49. The receptors for the sense of smell are special hair cells called c______ s. These are found in the o______ e_______, high in the n______ c_______ s in the head. The information received is transmitted by way of the o_______ nerves to the ______y bulbs and then into the opposite ______ hemisphere.

50. Describe the sensory receptors for the special sense of taste.

   The information received is transmitted to the opposite side of the brain by three ______ nerves.

51. What is the eyeball?

   The eyeball is shaped like a _____________________.
52. The outermost layer of the eyeball is colored ______ and is made up of very dense ______; it is known as the _____ . Its anterior portion is called the _______. The major focusing device for the eyeball is the _______.

53. The middle layer of the wall of the eyeball is known as the ___________. This layer is richly supplied with ___________ and pigmented with a _____ material.

54. The inner layer of the wall of the eyeball is known as the ___________. The actual photoreceptor elements are located at the ________ and the _______ s. These elements are the ______ s and the _______ s.

55. The elements which register colors are the ______ . However, ____ require more intense light than do _____. Rods register only ________________.

56. What are the fovea centralis and macula lutea?

.  

57. What is the blind spot?

.  

58. The thickening of the choroid layer around the edge of the lens is called the _________________. It includes radial muscle fibers making up the ______ muscle.

59. Describe the lens and the process of accommodation.

60. The space between the cornea and the iris is called the _______ ________. The space between the iris and the lens is called the ___________ _______. Together, these make up the space between the cornea and the lens, called the _______ _______ and filled with the ________ _______. This drains into the encircling ________________, located in the angle between the ________ and the ________. Behind the lens is a jellylike material called the _________________. It fills the ________ cavity of the eyeball.
61. The orbit is the cavity in the upper facial skull which contains the ______ and its _______. The orbit is shaped roughly like a _______.

62. Examples of the adnexa are the:
   a. __________________________.
   b. __________________________.
   c. __________________________.
   d. __________________________.
   e. __________________________.

63. Of the six extrinsic ocular muscles, four are called _____ muscles. Two are _______ muscles. The lateral rectus M. is on the _____ side of the eyeball. The superior rectus M. is _______ the eyeball. The medial rectus M. is on the _____ side of the eyeball. The inferior rectus M. is _______ the eyeball. The superior oblique and inferior oblique muscles approach the eyeball from the _______ side.

64. Attached to the margins of the orbit are the upper and lower _______. These have special hairs called ___________. The inner lining of the eyelids is continuous with the _________, a membrane over the anterior surface of the eyeball.

65. In the upper outer corner of the orbit is a lacrimal _____ d, which secretes a lacrimal ______ d, which is ultimately collected and delivered into the nasal chamber by the __________________ duct.

66. Neurons carry information from the photoreceptors located in the nervous ______. They leave the eyeball at the _______. Passing to the rear of the orbit, the neurons now belong to the _______ nerve (cranial nerve __). The optic nerve enters the cranial cavity by passing through the _______ canal. Beneath the brain, the optic nerves from both sides join to form the __________, in which half of the neurons from each optic nerve __________________________. From the optic chiasma, the right and left optic _______ s proceed to the brain proper.

67. The human ear has two major special sensory functions: ___________(_______y) and ___________ (_______e). The three parts of the human ear are the _______ (_______) ear, the _______ ear, and the _______ (_______) ear.
68. The external flap of the ear is called the ________ (_____). It directs airborne sound waves into the canal called the external auditory ______, which extends into the ______ portion of the skull.

69. Where is the tympanic membrane?

On the medial side of the tympanic membrane, there is a space within the temporal bone called the ________.

What are the auditory ossicles?

The auditory ossicles respond to a sound stimulus by _________. From the lateral to the medial ends, the names of the ossicles are: ________, ________, and _________. The auditory tube connects the middle ear cavity with the _________.

70. What is the bony labyrinth?

It has three ________ canals, a ________ (hallway), and a snail-shaped ________ portion.

What is the membranous labyrinth?

71. Where is the endolymph found?

Where is the perilymph found?

72. The cochlea is a ________ structure associated with ________ing. It has _______ turns. Its outer boundaries are formed by the snail-shaped portion of the _________.

MD0006 11-49
73. The central column of the cochlea is called the m_____. Extending from this central column is a spiral shelf of bone called the s_____ l_____. Connecting this shelf with the outer bony wall is a fibrous membrane called the b_____ membrane. This membrane forms the floor of the spiral portion of the membranous labyrinth called the c_____ d___. This contains a structure with hairs, sensory receptors of hearing; this structure is called the organ of _______.

74. Within the bony cochlea, the space above the cochlear duct is known as the ________________ and the space below is known as the ________________. Between the middle ear cavity and the upper space is an oval window called the fenestra ________. Between the middle ear cavity and the lower space is a round window called the fenestra ____________.

75. A sound stimulus is transferred from the stapes to the fluid ______ of the ________________. In response, the b____ membrane of the cochlea vibrates. The hair cells of the _____ of ____ are mechanically stimulated. This stimulation is transferred to the neurons of the ______ nerve, which passes out of the modiolus into the internal auditory ________ of the temporal bone. From here, the nerve enters the _______ cavity and goes to the ________.

76. The two sac-like portions of the membranous labyrinth are the ______ and the ________. They are filled with ____. On the wall of each sac is a collection of special hair cells known as the ___________, which serves as a receptor organ for _______ and linear ______ gravitational forces. The saccular macula and the utricular macula are oriented at more or less _____° angles to each other.

77. Extending from and opening into the utriculus are three hollow structures called the ______ ducts. The utriculus completes the circle for each ______. The three ducts are all oriented at ___° angles to each other. Where it opens into the utriculus, each semicircular duct ends in an enlargement called an _______________. Movement of the fluid endolymph bends the hairs of the ___________ in specific directions. These are responses to _______ and/or _______ kinetic gravitational forces.

78. Carrying the information from the maculae and the cristae to the brain is the ______ nerve. Contained in the same fibrous sheath from the membranous labyrinth to the brain are the v__________ and a______ nerves.
79. The simplest and lowest level of control is the ______ level. Producing wider reactions to stimuli are s______ reflexes. A number of nuclei in the hindbrain monitor and control v______l functions of the body, including r_______ and h______ b____. The facilitatory and inhibitory areas of the reticular formation monitor and control general body functions, including _________. The thalamus is a primary relay for information going to and from the _______ and _______. One of the most important integrators of motor activity of the body is the _____________.

80. In humans, the highest level of control is in the ___________. Here, we can clearly designate three levels of control:

   a. The first level is concerned with ______ activities of the body, as related to _____________, fear, and other emotions.

   b. At the second level, activities of the body are s__________d and repetitive in nature. An example is the sequence of muscle actions involved in w_______ing.

   c. At the third level, brand new solutions can be created. This is the v__________ level.

SOLUTIONS TO EXERCISES, LESSON 11

1. Two types of nervous tissues are neurons (nerve cells) and glia (neuroglia). The neuron is the basic structural unit of the nervous system. The glia are cells of supporting tissue for the nervous system. (para 11-1)

2. Nervous tissues are specialized to:
   a. Receive stimuli.
   b. Transmit information.
   c. Store information. (para 11-2)

3. A neuron is a nerve cell body and all of its processes. (para 11-3)

4. A dendrite carries impulses toward the cell body. (para 11-5a)

5. An axon is a neuron process which transmits information from the cell body to the next unit. (para 11-5b)

   Two poles: bipolar neuron.
   One pole: unipolar neuron. (para 11-6a)

7. Thickest: A.
   Medium: B.
   Thinnest: C. (para 11-6b)

8. From receptor organs to the CNS: sensory neurons.
   From the CNS to muscles and glands: motor neurons.
   From one neuron to another: interneurons. (para 11-6c)

9. The term "continuity without contact" refers to the fact that neurons do not actually touch. Thus, there is no electrical transmission of impulses from one neuron to the next. In fact, information is transferred across the synaptic cleft by chemicals called neurotransmitters. (para 11-7)

10. A synapse is a "connection" between two neurons. An axon terminates in tiny branches. At the end of each branch is a terminal bulb. Neurotransmitters are stored in bundles called synaptic vesicles located within each terminal bulb. The presynaptic membrane is the thickened layer of the terminal bulb which faces the synaptic cleft and through which pass the neurotransmitters before entering the synaptic cleft. The synaptic cleft is the space between the terminal bulb of the first neuron and the dendrite or cell body of the second neuron. The postsynaptic membrane is that portion of the membrane of the second neuron which lies near the terminal bulb of the first neuron. (para 11-7a)
11. A neuromuscular junction is a "connection" between the terminal of a motor neuron and a muscular fiber. Comparison: The neuromuscular junction has an organization identical to a synapse. However, the bulb is larger and protrudes into the surface of the muscle fiber. The postsynaptic membrane is also larger and has foldings. (para 11-7b)

12. The major divisions of the human nervous system are the central nervous system (CNS), the peripheral nervous system (PNS), and the autonomic nervous system (ANS). The CNS is made up of the brain and the spinal cord. (para 11-8)

13. The three major subdivisions of the human brain are the brainstem, the cerebellum, and the cerebrum. The brainstem is that part of the brain remaining after removal of the cerebrum and cerebellum. It is the basal portion. Together with the spinal cord, it is known as the neuraxis. (para 11-9a)

14. The cerebellum is a spherical mass of nervous tissue attached to and covering the hindbrainstem. Its three major parts are the vermis and right and left cerebellar hemispheres. In addition, the cerebellum has three pairs of stem-like connecting parts called peduncles. The outer cortex is composed of gray matter, which is the cell bodies of neurons. More central is the white matter, which is the myelinated processes of neurons. The cerebellum is the primary coordinator/integrator of motor actions of the body. (para 11-9b)

15. The cerebrum consists of two very much enlarged hemispheres connected to each other by a special structure called the corpus callosum. Each cerebral hemisphere is connected to the brainstem by a cerebral peduncle. The surface of each cerebral hemisphere is subdivided into areas known as lobes. The names of the four lobes are frontal, parietal, occipital, and temporal. (para 11-9c)

16. The space separating the two cerebral hemispheres is called the longitudinal fissure. The shallow grooves in the surface of the cerebrum are called sulci. The ridges outlined by the sulci are called gyri. (para 11-9c(1))

17. The gray outer layer of each hemisphere is the cerebral cortex. Deeper within the cerebral hemispheres, the tissue is colored white. The "gray matter" represents the cell bodies of the neurons. The "white matter" represents the axons. (para 11-9c(2))

18. Groups of related functions are associated with specific areas of the cerebral cortex. For example, centers of speech and hearing are located along the lateral sulcus. Vision is centered in the occipital lobe. Sensory and motor functions are located along the central sulcus. (para 11-9c(3))
19. The ventricles of the brain are interconnected hollow spaces filled with CSF. The right and left lateral ventricles are found in the cerebral hemispheres. The lateral ventricles are connected to the third ventricle by the interventricular foramen. The third ventricle is located in the forebrainstem. The third and fourth ventricles are connected by the cerebral aqueduct. The fourth ventricle is located in the hindbrainstem. The fourth ventricle is continuous with the part of the spinal cord known as the central canal. (para 11-9d)

20. The spinal cord, located within the spinal canal, is continuous with the brainstem. The spinal cord has two enlargements. One, associated with nerves for the upper members, is called the cervical enlargement. The other, associated with nerves for the lower members, is called the lumbosacral enlargement. Nerves arising from the spinal cord are called spinal nerves. There are 31 pairs of spinal nerves. (para 11-10a)

21. In the cross section of the spinal cord, one can see a central region of gray matter shaped like an H. Each arm of this figure is called a horn. The connecting link is called the gray commissure. These horns are actually sections of the gray columns. Since a column of white matter is a large bundle of processes, it is called a funiculus. (para 11-10b)

22. The skeletal covering for the brain is provided by bones of the cranium. The overall skeletal structure covering the spinal cord is the vertebral column (spine). (para 11-11a)

23. The brain and spinal cord have three different membranes surrounding them called meninges. The tough outer covering for the CNS is the dura mater. Beneath it is the subdural space. The fine second membrane is called the arachnoid mater. Beneath it is the subarachnoid space, which is filled with CSF. The delicate membrane applied directly to the surface of the brain and spinal cord is called the pia mater. (para 11-11b)

24. The two main pairs of arteries supplying oxygenated blood to the brain are the internal carotid and the vertebral arteries. Beneath the brain, branches of these arteries join to form a circle, called the cerebral circle (of Willis). The main pair of veins carrying blood back toward the heart is the internal jugular veins. The blood supply of the spinal cord is by way of a combination of three longitudinal arteries running along its length and reinforced by segmental arteries from the sides. (para 11-12)

25. Found in the cavities of the CNS is a clear fluid called cerebrospinal fluid (CSF). This fluid is found in the ventricles of the brain, the subarachnoid space, and the spinal cord’s central canal. Special collections of arterial capillaries found in the roofs of the third and fourth ventricles are called choroid plexuses. These structures continuously produce CSF from the plasma of the blood. (para 11-13)
26. As CSF is produced by the choroid plexuses, it flows into all four ventricles. CSF from the lateral ventricles flows into the third ventricle and then through the cerebral aqueduct into the fourth ventricle. By passing through three small holes in the roof of the fourth ventricle, CSF enters the subarachnoid space. From here, the CSF is transported through the arachnoid villi into the venous sinuses.

(para 11-13b)

27. The peripheral nervous system is that portion of the nervous system which generally provides commands for skeletal muscles and other striated muscles and carries sensory information from the periphery of the body. A nerve is a collection of neuron processes, together and outside the CNS.

(para 11-14a)

28. The 12 pairs of nerves attached to the right and left sides of the brainstem are called cranial nerves. Each such nerve is identified by a Roman numeral in order from I to XII and an individual name. Attached to the sides of the spinal cord are 31 pairs of spinal nerves. For each, the region is designated by a letter; within each region, a nerve pair is identified by an Arabic numeral.

(para 11-14c)

29. Like a tree, a typical spinal nerve has roots, a trunk, and branches (called rami). Coming off of the posterior and anterior sides of the spinal cord are the posterior and anterior roots of the spinal nerve. An enlargement on the posterior root is the posterior root ganglion. A ganglion is a collection of neuron cell bodies, together, outside the CNS. Laterally, the posterior and anterior roots of the spinal nerve join to form the spinal nerve trunk. The spinal nerve trunk of each spinal nerve is located in the corresponding intervertebral foramen of the vertebral column. As the nerve trunk emerges laterally, it divides into the anterior and posterior rami.

(para 11-15a)

30. If it carries information from the periphery to the CNS, it is an afferent (sensory) neuron. If it carries information from the CNS to a muscle or gland, it is an efferent (motor) neuron.

(para 11-15b)

31. An automatic reaction to a stimulus is referred to as a reflex. The pathway from the receptor organ to the reacting muscle is called the reflex arc.

(para 11-15c(1))

32. The pathway of a general reflex arc involves a minimum of five structures. The stimulus is received by a receptor organ. The information is transmitted to the CNS by the afferent (sensory) neuron. Within the spinal cord, there is a special neuron connecting the afferent neuron to the efferent neuron; this special connecting neuron is called the interneuron (or internuncial neuron). Carrying the appropriate command from the spinal cord to the reacting muscle is efferent (motor) neuron. The reacting muscle is called the effector organ.

(para 11-15c(2))

33. The autonomic nervous system is that portion of the nervous system generally concerned with commands for smooth muscle, cardiac muscle, and glands.

(para 11-16)
34. In the ANS, the number of neurons connecting the CNS with a visceral organ is always two. The cell bodies of the second neurons form a collection outside the CNS, called a ganglion. The first neuron extends from the CNS to the ganglion and is therefore called the preganglionic neuron. Cell bodies of the second neurons make up the ganglion. The second neuron's processes extend from the ganglion to the visceral organ. Thus, the second neuron is called the post-ganglionic neuron. (para 11-16b)

35. The efferent pathways of the ANS fall into two major divisions. The one most active during a "fight-or-flight" reaction is the thoraco-lumbar outflow (sympathetic nervous system). The other is the cranio-sacral outflow (parasympathetic nervous system). (para 11-16c)

36. The intermediolateral gray columns from the T-1 to the L-2 levels of the spinal cord are made up of the cell bodies of the preganglionic sympathetic neurons. The sympathetic ganglia are made up of the post-ganglionic sympathetic neurons. The sympathetic NS activates those visceral organs needed to mobilize energy for action. It deactivates those which are not needed. (para 11-17)

37. Four pairs of nuclei in the brainstem and the intermediolateral gray columns at the S-2 through S-4 levels of the spinal cord are made up of the cell bodies of the preganglionic parasympathetic neurons. The intramural ganglia within the walls of the central visceral organs are made up of the cell bodies of the post-ganglionic parasympathetic neurons. As compared to that of the sympathetic NS, the parasympathetic NS has the opposite effect on visceral organs. (para 11-18)

38. A pathway is the series of nervous structures utilized in the transmission of an item of information. (para 11-19a(1))

39. The neuraxis is the brainstem and the spinal cord, considered together as one structure. (para 11-19a(2))

40. A sensory pathway is a series of nervous structures used to transmit information from the body to the CNS. (para 11-19b(1))

41. A motor pathway is a series of nervous structures used to transmit information from the CNS to the body. (para 11-19b(2))

42. The human nervous system has several levels of control. The lowest level is the simple reflex arc. The highest level is the conscious level. Between, there are several progressively higher levels. All information input and all information output are monitored and evaluated. (para 11-19c) The right half of the brain controls the left side of the body. The left half of the brain controls the right side of the body. (para 11-20)
44. A pyramidal motor pathway is primarily concerned with volitional (voluntary) control of body parts, particularly the fine movements of hands. These pathways are called pyramidal because their neuron processes help to make up structures in the base of the brain called pyramids. (para 11-20a)

45. An extrapyramidal pathway is primarily concerned with automatic (nonvolitional) control of body parts for purposes of coordination. (para 11-20b)

46. Examples of general senses are:
   a. Pain.
   b. Temperature (warm and cold).
   c. Touch (light and deep).
   d. Proprioception ("body sense"). (para 11-21c)

47. Examples of special senses are:
   a. Smell (olfaction).
   b. Taste (gustation).
   c. Vision.
   d. Hearing (auditory).
   e. Equilibrium. (para 11-21d)

48. The general sensory pathway is from the receptor organ, via the PNS nerves, to the CNS. This general pathway then ascend fiber tracts in the neuraxis. The pathway ends in the central area of the opposite cerebral hemisphere. (para 11-21e)

49. The receptors for the sense of smell are special hair cells called chemoreceptors. These are found in the olfactory epithelium, high in the nasal chambers in the head. The information received is transmitted by way of the olfactory nerves to the olfactory bulbs and then into the opposite cerebral hemisphere. (paras 11-22, 11-23)

50. Special hair cells (chemoreceptors) are found in the taste buds, scattered over the tongue and the rear of the mouth. These cells, which react to dispersed or dissolved food molecules, are the sensory receptors for the special sense of taste. The information received is transmitted to the opposite side of the brain by three cranial nerves. (paras 11-24, 11-25)

51. The eyeball is the sense organ containing the receptor tissues for the special sense of vision. The eyeball is shaped like a bulb (or sphere). (paras 11-26c, 11-27a)
52. The outermost layer of the eyeball is colored white and is made up of very dense FCT; it is known as the sclera, scleral coat, or fibrous tunic. Its anterior portion is called the cornea. The major focusing device for the eyeball is the cornea. (para 11-27b(1))

53. The middle layer of the wall of the eyeball is known as the choroid, choroid coat, or vascular tunic. This layer is richly supplied with blood vessels and pigmented with a black material. (para 11-27b(2))

54. The inner layer of the wall of the eyeball is known as the retina, retinal coat, or internal tunic. The actual photoreceptor elements are located at the back and the sides. These elements are the rods and the cones. (para 11-27b(3))

55. The elements which register colors are the cones. However, cones require more intense light than do rods. Rods register only black and white. (para 11-27c(1)(a))

56. The fovea centralis is a small depression at the posterior end of the eyeball opposite the pupil. The macula lutea is a small yellow area of the retina where vision is sharpest. It includes the fovea centralis. (para 11-27c(1)(b))

57. The blind spot is the point of exit of the optic nerve, at the posterior end of the eyeball where there are no rods and cones. (para 11-27c(1)(c))

58. The thickening of the choroid layer around the edge of the lens is called the ciliary body. It includes radial muscle fibers making up the ciliary muscle. (para 11-27c(2))

59. The lens is biconvex. The anterior surface is flatter than the posterior surface. The lens is transparent and elastic. Its thickness varies with contraction or relaxation of the ciliary muscle. Accommodation is the process in which close objects are seen more clearly; it involves contraction of the ciliary muscle, reduction in pupil size, and convergence of the lines of sight. (para 11-27c(4))

60. The space between the cornea and the iris is called the anterior chamber. The space between the iris and the lens is called the posterior chamber. Together, these make up the space between the cornea and the lens called the anterior cavity and filled with the aqueous humor. This drains into the encircling canal of Schlemm, located in the angle between the cornea and the iris. Behind the lens is a jellylike material called the vitreous body. It fills the posterior cavity of the eyeball. (para 11-27c(6), (7))

61. The orbit is the cavity in the upper facial skull which contains the eyeball and its adnexa. The orbit is shaped roughly like a cone. (para 11-28a)
62. Examples of the adnexa are the:

a. **Extrinsic ocular muscles.**

b. **Eyelids.**

c. **Lacrimal apparatus.**

d. **Eyebrow.**

e. **Optic nerve.** (para 11-29)

63. Of the six extrinsic ocular muscles, four are called **recti** muscles. Two are **oblique** muscles. The lateral rectus M. is on the **outer** side of the eyeball. The superior rectus M. is **above** the eyeball. The medial rectus M. is on the **inner** side of the eyeball. The inferior rectus M. is **below** the eyeball. The superior oblique and inferior oblique muscles approach the eyeball from the **medial** side. (para 11-29a)

64. Attached to the margins of the orbit are the upper and lower **eyelids.** These have special hairs called **eyelashes.** The inner lining of the eyelids is continuous with the **conjunctiva,** a membrane over the anterior surface of the eyeball. (para 11-29b)

65. In the upper outer corner of the orbit is a **lacrimal gland,** which secretes a **lacrimal fluid,** which is ultimately collected and delivered into the nasal chamber by the **nasolacrimal duct.** (para 11-29c)

66. Neurons carry information from the photoreceptors located in the nervous retina. They leave the eyeball at the **blind spot.** Passing to the rear of the orbit, the neurons now belong to the **optic nerve** (cranial nerve II). The optic nerve enters the cranial cavity by passing through the **optic canal.** Beneath the brain, the optic nerves from both sides join to form the **optic chiasma,** in which half of the neurons from each optic nerve **cross to the opposite side.** From the optic chiasma, the right and left optic **tracts** proceed to the brain proper. (para 11-29e)

67. The human ear has two major special sensory functions: hearing (auditory) and **equilibrium** (balance). The three parts of the human ear are the external (outer) ear, the **middle** ear, and the internal (inner) ear. (para 11-30)

68. The external flap of the ear is called the **auricle** (pinna). It directs airborne sound waves into the canal called the **external auditory meatus,** which extends into the **temporal** portion of the skull. (para 11-31)

69. The tympanic membrane is between the external auditory meatus and the **middle ear cavity.** On the medial side of the tympanic membrane, there is a space within the temporal bone called the **middle ear cavity.** The auditory ossicles are three very small bones linking the tympanic membrane to the medial wall of the **middle ear cavity.** The auditory ossicles respond to a sound stimulus by **vibrating** (mechanically oscillating). From the lateral to the medial ends, the names of the
Ossicles are: malleus, incus, and stapes. The auditory tube connects the middle ear cavity with the nasopharynx. (para 11-32)

70. The bony labyrinth is a complex cavity within the temporal bone. It has three semi-circular canals, a vestibule (hallway), and a snail-shaped cochlear portion. The membranous labyrinth is a hollow tubular structure suspended within the bony labyrinth. (para 11-33a)

71. The endolymph fills the space within the membranous labyrinth. The perilymph fills the space between the membranous labyrinth and the bony labyrinth. (para 11-33b)

72. The cochlea is a spiral structure associated with hearing. It has 2-1/2 turns. Its outer boundaries are formed by the snail-shaped portion of the bony labyrinth. (para 11-33c)

73. The central column of the cochlea is called the modiolus. Extending from this central column is a spiral shelf of bone called the spiral lamina. Connecting this shelf with the outer bony wall is a fibrous membrane called the basilar membrane. This membrane forms the floor of the spiral portion of the membranous labyrinth called the cochlear duct. This contains a structure with hairs, sensory receptors of hearing; this structure is called the organ of Corti. (para 11-33c(1))

74. Within the bony cochlea, the space above the cochlear duct is known as the scala vestibuli and the space below is known as the scala tympani. Between the middle ear cavity and the upper space is an oval window called the fenestra vestibuli. Between the middle ear cavity and the lower space is a round window called the fenestra cochleae. (para 11-33c(2), (3))

75. A sound stimulus is transferred from the stapes to the fluid perilymph of the scala vestibuli. In response, the basilar membrane of the cochlea vibrates. The hair cells of the organ of Corti are mechanically stimulated. This stimulation is transferred to the neurons of the acoustic nerve, which passes out of the modiolus into the internal auditory meatus of the temporal bone. From here, the nerve enters the cranial cavity and goes to the brain. (para 11-33d)

76. The two sac-like portions of the membranous labyrinth are the saccusculus and the utriculus. They are filled with endolymph. On the wall of each sac is a collection of special hair cells known as the macula, which serves as a receptor organ for static and linear kinetic gravitational forces. The saccular macula and the utricular macula are oriented at more or less 90° angles to each other. (para 11-35)

77. Extending from and opening into the utriculus are three hollow structures called the semicircular ducts. The utriculus completes the circles for each duct. The three ducts are all oriented at 90° angles to each other. Where it opens into the utriculus, each semicircular duct ends in an enlargement called an ampulla.
Movement of the fluid endolymph bends the hairs of the crista in specific directions. These are responses to linear and/or angular kinetic gravitational forces. (para 11-36b)

78. Carrying the information from the maculae and the cristae to the brain is the vestibular nerve. Contained in the same fibrous sheath from the membranous labyrinth to the brain are the vestibular and auditory nerves. (para 11-37)

79. The simplest and lowest level of control is the reflex arc. Producing wider reactions to stimuli are segmental reflexes. A number of nuclei in the hindbrain monitor and control visceral functions of the body, including respiration and heartbeat. The facilitatory and inhibitory areas of the reticular formation monitor and control general body functions, including sleep. The thalamus is a primary relay for information going to and from the cerebrum and cerebellum. One of the most important integrators of motor activity of the body is the cerebellum. (para 11-39)

80. In humans, the highest level of control is in the cerebrum. Here, we can clearly designate three levels of control.

a. The first level is concerned with visceral activities of the body, as related to fight-or-flight, fear, and other emotions.

b. At the second level, activities of the body are standardized and repetitive in nature. An example is the sequence of muscle actions involved in walking.

c. At the third level, brand new solutions can be created. This is the volitional level. (para 11-39g)
